

Features

- In-System Programmable PROMs for Configuration of Xilinx FPGAs
- Low-Power Advanced CMOS FLASH Process
- Endurance of 20,000 Program/Erase Cycles
- Operation over Full Industrial Temperature Range (–40°C to +85°C)
- Available in small footprint packages: VO20, VO48, and FS48
- IEEE Standard 1149.1/1532 Boundary-Scan (JTAG) Support for Programming, Prototyping, and Testing
- JTAG Command Initiation of Standard FPGA Configuration
- Cascadable for Storing Longer or Multiple Bitstreams
- Dedicated Boundary-Scan (JTAG) I/O Power Supply (V_{CCJ})
- I/O Pins Compatible with Voltage Levels Ranging From 1.5V to 3.3V
- Design Support Using the Xilinx Alliance ISE and Foundation ISE Series Software Packages
- XCF01S/XCF02S/XCF04S
 - 3.3V supply voltage
 - Serial FPGA configuration interface
- XCF08P/XCF16P/XCF32P
 - 1.8V supply voltage
 - Serial or parallel FPGA configuration interface
 - Design revision technology enables storing and accessing multiple design revisions for configuration
 - Built-in data decompressor compatible with Xilinx advanced compression technology

Table 1: Platform Flash PROM Features

| | Density | V_{CCINT} | V_{CCO} / V_{CCJ} Range | Packages | JTAG ISP Programming | Serial Configuration | Parallel Configuration | Design Reversioning | Compression |
|--------|---------|-------------|------------------------------|--------------|-------------------------|-------------------------|---------------------------|------------------------|-------------|
| XCF01S | 1 Mbit | 3.3V | 1.8V - 3.3V | VO20 | √ | √ | | | |
| XCF02S | 2 Mbit | 3.3V | 1.8V - 3.3V | VO20 | √ | √ | | | |
| XCF04S | 4 Mbit | 3.3V | 1.8V - 3.3V | VO20 | √ | √ | | | |
| XCF08P | 8 Mbit | 1.8V | 1.5V - 3.3V | VO48 FS48 | √ | √ | √ | √ | √ |
| XCF16P | 16 Mbit | 1.8V | 1.5V - 3.3V | VO48 FS48 | √ | √ | √ | √ | √ |
| XCF32P | 32 Mbit | 1.8V | 1.5V - 3.3V | VO48 FS48 | √ | √ | √ | √ | √ |

Description

Xilinx introduces the Platform Flash series of in-system programmable configuration PROMs. Available in 1 to 32 Megabit (Mbit) densities, these PROMs provide an easy-to-use, cost-effective, and reprogrammable method for storing large Xilinx FPGA configuration bitstreams. The Platform Flash PROM series includes both the 3.3V XCFxxS PROM and the 1.8V XCFxxP PROM. The XCFxxS version includes 4-Mbit, 2-Mbit, and 1-Mbit PROMs that support Master Serial and Slave Serial FPGA configuration modes (Figure 1). The XCFxxP version includes 32-Mbit, 16-Mbit, and 8-Mbit PROMs that support Master Serial,

Slave Serial, Master SelectMAP, and Slave SelectMAP FPGA configuration modes (Figure 2). A summary of the Platform Flash PROM family members and supported features is shown in Table 1.

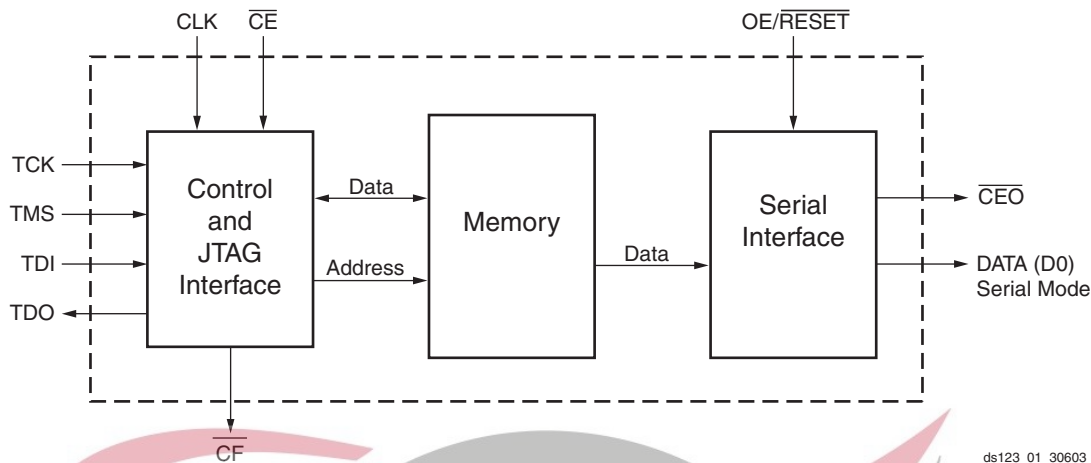

Figure 1: XCFxxS Platform Flash Block Diagram

ds123_01_30603

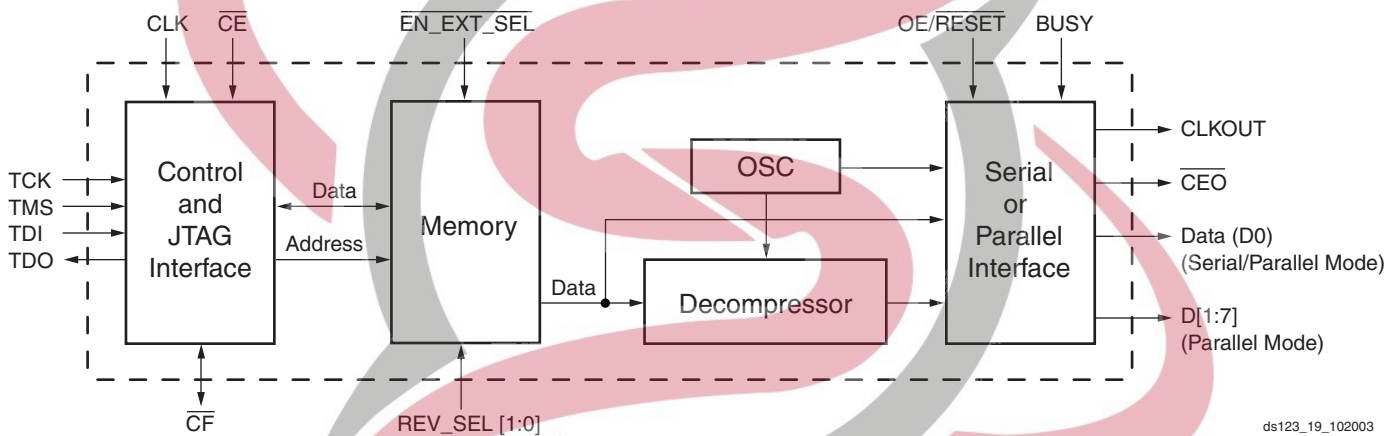

Figure 2: XCFxxP Platform Flash Block Diagram

ds123_19_102003

When the FPGA is in Master Serial mode, it generates a configuration clock that drives the PROM. A short access time after \overline{CE} and OE are enabled, data is available on the PROM DATA (D0) pin that is connected to the FPGA DIN pin. New data is available a short access time after each rising clock edge. The FPGA generates the appropriate number of clock pulses to complete the configuration.

When the FPGA is in Slave Serial mode, the PROM and the FPGA are both clocked by an external clock source, or optionally, for the XCFxxP PROM only, the PROM can be used to drive the FPGAs configuration clock.

The XCFxxP version of the Platform Flash PROM also supports Master SelectMAP and Slave SelectMAP (or Slave Parallel) FPGA configuration modes. When the FPGA is in Master SelectMAP mode, the FPGA generates a configuration clock that drives the PROM. When the FPGA is in Slave SelectMAP Mode, either an external oscillator generates the configuration clock that drives the PROM and the FPGA, or optionally, the XCFxxP PROM can be used to drive the FPGAs configuration clock. After \overline{CE} and OE are enabled, data is available on the PROMs DATA (D0-D7)

pins. New data is available a short access time after each rising clock edge. The data is clocked into the FPGA on the following rising edge of the CCLK. A free-running oscillator can be used in the Slave Parallel /Slave SelectMAP mode.

The XCFxxP version of the Platform Flash PROM provides additional advanced features. A built-in data decompressor supports utilizing compressed PROM files, and design revisioning allows multiple design revisions to be stored on a single PROM or stored across several PROMs. For design revisioning, external pins or internal Control bits are used to select the active design revision.

Multiple Platform Flash PROM devices can be cascaded to support the larger configuration files required when targeting larger FPGA devices or targeting multiple FPGAs daisy chained together. When utilizing the advanced features for the XCFxxP Platform Flash PROM, such as design revisioning, programming files which span cascaded PROM devices can only be created for cascaded chains containing only XCFxxP PROMs. If the advanced XCFxxP features are not enabled, then the cascaded chain can include both XCFxxP and XCFxxS PROMs.

The Platform Flash PROMs are compatible with all of the existing FPGA device families. A reference list of Xilinx FPGAs and the respective compatible Platform Flash PROMs is given in Table 2. A list of Platform Flash PROMs and their capacities is given in Table 3.

Programming

In-System Programming

In-System Programmable PROMs can be programmed individually, or two or more can be daisy-chained together and programmed in-system via the standard 4-pin JTAG protocol as shown in Figure 3. In-system programming offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices. The programming data sequence is delivered to the device using either Xilinx iMPACT software and a Xilinx download cable, a third-party JTAG development system, a JTAG-compatible board tester, or a simple microprocessor interface that emulates the JTAG instruction sequence. The iMPACT software also outputs serial vector format (SVF) files for use with any tools that accept SVF format, including automatic test equipment. During in-system programming, the \overline{CEO} output is driven High. All other outputs are held in a high-impedance state or held at clamp levels during in-system programming. In-system programming is fully supported across the recommended operating voltage and temperature ranges.

Figure 3: JTAG In-System Programming Operation
(a) Solder Device to PCB
(b) Program Using Download Cable

$\overline{OE}/\overline{RESET}$

The 1/2/4 Mbit XCFxxS Platform Flash PROMs in-system programming algorithm requires issuance of a reset that causes $\overline{OE}/\overline{RESET}$ to pulse Low.

External Programming

Xilinx reprogrammable PROMs can also be programmed by the Xilinx MultiPRO Desktop Tool or a third-party device

programmer. This provides the added flexibility of using pre-programmed devices with an in-system programmable option for future enhancements and design changes.

Reliability and Endurance

Xilinx in-system programmable products provide a guaranteed endurance level of 20,000 in-system program/erase cycles and a minimum data retention of 20 years. Each device meets all functional, performance, and data retention specifications within this endurance limit.

Design Security

The Xilinx in-system programmable Platform Flash PROM devices incorporate advanced data security features to fully protect the FPGA programming data against unauthorized reading via JTAG. The XCFxxP PROMs can also be programmed to prevent inadvertent writing via JTAG. Table 4 and Table 5 show the security settings available for the XCFxxS PROM and XCFxxP PROM, respectively.

Read Protection

The read protect security bit can be set by the user to prevent the internal programming pattern from being read or copied via JTAG. Read protection does not prevent write operations. For the XCFxxS PROM, the read protect security bit is set for the entire device, and resetting the read protect security bit requires erasing the entire device. For the XCFxxP PROM the read protect security bit can be set for individual design revisions, and resetting the read protect bit requires erasing the particular design revision.

Write Protection

The XCFxxP PROM device also allows the user to write protect (or lock) a particular design revision to prevent inadvertent erase or program operations. Once set, the write protect security bit for an individual design revision must be reset (using the UNLOCK command followed by ISC_ERASE command) before an erase or program operation can be performed.

Table 4: XCFxxS Device Data Security Options

| Read Protect | Read/Verify Inhibited | Program Inhibited | Erase Inhibited |
|-----------------|-----------------------|-------------------|-----------------|

IEEE 1149.1 Boundary-Scan (JTAG)

The Platform Flash PROM family is IEEE Standard 1532 in-system programming compatible, and is fully compliant with the IEEE Std. 1149.1 Boundary-Scan, also known as JTAG, which is a subset of IEEE Std. 1532 Boundary-Scan. A Test Access Port (TAP) and registers are provided to support all required boundary scan instructions, as well as many of the optional instructions specified by IEEE Std. 1149.1. In addition, the JTAG interface is used to implement in-system programming (ISP) to facilitate configuration, erasure, and verification operations on the Platform Flash PROM device. Table 6 lists the required and optional boundary-scan instructions supported in the Platform Flash PROMs. Refer to the IEEE Std. 1149.1 specification for a complete description of boundary-scan architecture and the required and optional instructions.

Instruction Register

The Instruction Register (IR) for the Platform Flash PROM is connected between TDI and TDO during an instruction scan sequence. In preparation for an instruction scan sequence, the instruction register is parallel loaded with a fixed instruction capture pattern. This pattern is shifted out onto TDO (LSB first), while an instruction is shifted into the instruction register from TDI.

XCFxxS Instruction Register (8 bits wide)

The Instruction Register (IR) for the XCFxxS PROM is eight bits wide and is connected between TDI and TDO during an instruction scan sequence. The detailed composition of the instruction capture pattern is illustrated in Figure 4.

The instruction capture pattern shifted out of the XCFxxS device includes IR[7:0]. IR[7:5] are reserved bits and are set

to a logic "0". The ISC Status field, IR[4], contains logic "1" if the device is currently in In-System Configuration (ISC) mode; otherwise, it contains logic "0". The Security field, IR[3], contains logic "1" if the device has been programmed with the security option turned on; otherwise, it contains logic "0". IR[2] is unused, and is set to '0'. The remaining bits IR[1:0] are set to '01' as defined by IEEE Std. 1149.1.

XCFxxP Instruction Register (16 bits wide)

The Instruction Register (IR) for the XCFxxP PROM is sixteen bits wide and is connected between TDI and TDO during an instruction scan sequence. The detailed composition of the instruction capture pattern is illustrated in Figure 5.

The instruction capture pattern shifted out of the XCFxxP device includes IR[15:0]. IR[15:9] are reserved bits and are set to a logic "0". The ISC Error field, IR[8:7], contains a "10" when an ISC operation is a success, otherwise a "01" when an In-System Configuration (ISC) operation fails. The Erase/Program (ER/PROG) Error field, IR[6:5], contains a "10" when an erase or program operation is a success, otherwise a "01" when an erase or program operation fails. The Erase/Program (ER/PROG) Status field, IR[4], contains a logic "1" when the device is busy performing an erase or programming operation, otherwise, it contains a logic "0". The ISC Status field, IR[3], contains logic "1" if the device is currently in In-System Configuration (ISC) mode; otherwise, it contains logic "0". The DONE field, IR[2], contains logic "1" if the sampled design revision has been successfully programmed; otherwise, a logic "0" indicates incomplete programming. The remaining bits IR[1:0] are set to '01' as defined by IEEE Std. 1149.1.

Table 6: Platform Flash PROM Boundary Scan Instructions

| Boundary-Scan Command | XCFxxS IR[7:0] (hex) | XCFxxP IR[15:0] (hex) | Instruction Description |
|------------------------------|----------------------|-----------------------|--|
| Required Instructions | | | |
| BYPASS | FF | FFFF | Enables BYPASS |
| SAMPLE/PRELOAD | 01 | 0001 | Enables boundary-scan SAMPLE/PRELOAD operation |
| EXTEST | 00 | 0000 | Enables boundary-scan EXTEST operation |

Table 6: Platform Flash PROM Boundary Scan Instructions (Continued)

| Boundary-Scan Command | XCFxxS IR[7:0] (hex) | XCFxxP IR[15:0] (hex) | Instruction Description |
|--|-------------------------|--------------------------|---|
| Optional Instructions | | | |
| CLAMP | FA | 00FA | Enables boundary-scan CLAMP operation |
| HIGHZ | FC | 00FC | Places all outputs in high-impedance state simultaneously |
| IDCODE | FE | 00FE | Enables shifting out 32-bit IDCODE |
| USERCODE | FD | 00FD | Enables shifting out 32-bit USERCODE |
| Platform Flash PROM Specific Instructions | | | |
| CONFIG | EE | 00EE | Initiates FPGA configuration by pulsing \overline{CF} pin Low once. (For the XCFxxP this command also resets the selected design revision based on either the external REV_SEL[1:0] pins or on the internal design revision selection bits.) ⁽¹⁾ |

Notes:

1. For more information see Initiating FPGA Configuration.

Figure 5: XCFxxP Instruction Capture Values Loaded into IR as part of an Instruction Scan Sequence

Boundary Scan Register

The boundary-scan register is used to control and observe the state of the device pins during the EXTEST, SAMPLE/PRELOAD, and CLAMP instructions. Each output pin on the Platform Flash PROM has two register stages which contribute to the boundary-scan register, while each input pin has only one register stage. The bidirectional pins have a total of three register stages which contribute to the boundary-scan register. For each output pin, the register stage nearest to TDI controls and observes the output state, and the second stage closest to TDO controls and observes the High-Z enable state of the output pin. For each input pin, a single register stage controls and observes the input state of the pin. The bidirectional pin combines the three bits, the

input stage bit is first, followed by the output stage bit and finally the output enable stage bit. The output enable stage bit is closest to TDO.

See the XCFxxS/XCFxxP Pin Names and Descriptions Tables in the **Pinouts and Pin Descriptions** section for the boundary-scan bit order for all connected device pins, or see the appropriate BSDL file for the complete boundary-scan bit order description under the "attribute BOUNDARY_REGISTER" section in the BSDL file. The bit assigned to boundary-scan cell "0" is the LSB in the boundary-scan register, and is the register bit closest to TDO.

Identification Registers

IDCODE Register

The IDCODE is a fixed, vendor-assigned value that is used to electrically identify the manufacturer and type of the device being addressed. The IDCODE register is 32 bits wide. The IDCODE register can be shifted out for examination by using the IDCODE instruction. The IDCODE is available to any other system component via JTAG. Table 7 lists the IDCODE register values for the Platform Flash PROMs.

The IDCODE register has the following binary format:

vvvv:ffff:ffff:aaaa:aaaa:cccc:cccc:ccc1

where

v = the die version number

f = the PROM family code

a = the specific Platform Flash PROM product ID

c = the Xilinx manufacture's ID

The LSB of the IDCODE register is always read as logic "1" as defined by IEEE Std. 1149.1.

Table 7: IDCODES Assigned to Platform Flash PROMs

| Device | IDCODE ⁽¹⁾ (hex) |
|--------|-----------------------------|
| XCF01S | 05044093 |
| XCF02S | 05045093 |
| XCF04S | 05046093 |
| XCF08P | 05057093 |
| XCF16P | 05058093 |
| XCF32P | 05059093 |

Notes:

1. The first four bits indicate the die version number, and may vary.

USERCODE Register

The USERCODE instruction gives access to a 32-bit user programmable scratch pad typically used to supply information about the device's programmed contents. By using the USERCODE instruction, a user-programmable identification code can be shifted out for examination. This code is loaded into the USERCODE register during programming of the Platform Flash PROM. If the device is blank or was not loaded during programming, the USERCODE register contains FFFFFFFFh.

Customer Code Register

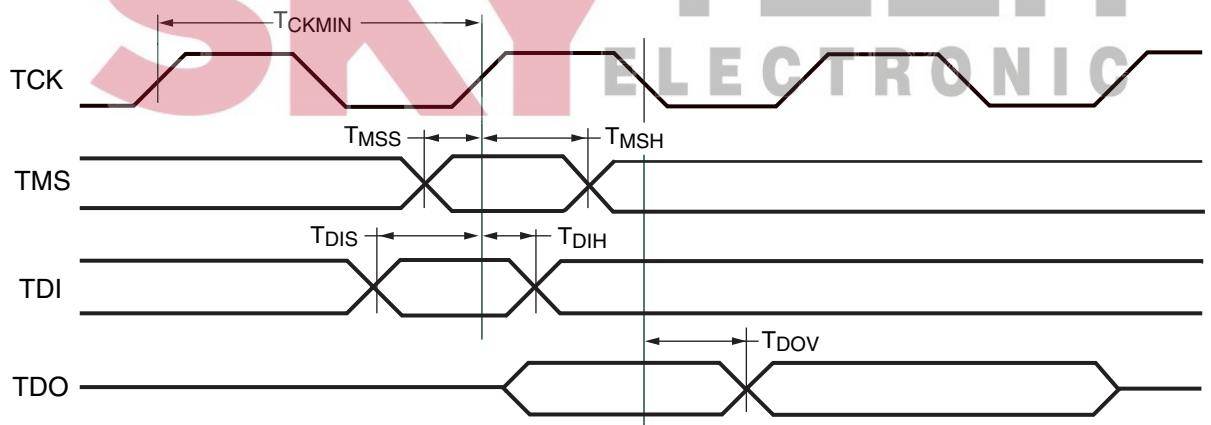

For the XCFxxP Platform Flash PROM, in addition to the USERCODE, a unique 32-byte Customer Code can be assigned to each design revision enabled for the PROM. The Customer Code is set during programming, and is typically used to supply information about the design revision contents. A private JTAG instruction is required to read the Customer Code. If the PROM is blank, or the Customer Code for the selected design revision was not loaded during programming, or if the particular design revision is erased, the Customer Code will contain all ones.

Platform Flash PROM TAP Characteristics

The Platform Flash PROM family performs both in-system programming and IEEE 1149.1 boundary-scan (JTAG) testing via a single 4-wire Test Access Port (TAP). This simplifies system designs and allows standard Automatic Test Equipment to perform both functions. The AC characteristics of the Platform Flash PROM TAP are described as follows.

TAP Timing

Figure 6 shows the timing relationships of the TAP signals. These TAP timing characteristics are identical for both boundary-scan and ISP operations.

DS026_04_020300

Figure 6: Test Access Port Timing

TAP AC Parameters

Table 8 shows the timing parameters for the TAP waveforms shown in Figure 6.

Table 8: Test Access Port Timing Parameters

| Symbol | Parameter | Min | Max | Units |
|--------------|--|-----|-----|-------|
| T_{CKMIN1} | TCK minimum clock period when $V_{CCJ} = 2.5V$ or $3.3V$ | 100 | - | ns |
| T_{CKMIN2} | TCK minimum clock period, Bypass Mode, when $V_{CCJ} = 2.5V$ or $3.3V$ | 50 | - | ns |
| T_{MSS} | TMS setup time when $V_{CCJ} = 2.5V$ or $3.3V$ | 10 | - | ns |
| T_{MSH} | TMS hold time when $V_{CCJ} = 2.5V$ or $3.3V$ | 25 | - | ns |
| T_{DIS} | TDI setup time when $V_{CCJ} = 2.5V$ or $3.3V$ | 10 | - | ns |
| T_{DIH} | TDI hold time when $V_{CCJ} = 2.5V$ or $3.3V$ | 25 | - | ns |
| T_{DOV} | TDO valid delay when $V_{CCJ} = 2.5V$ or $3.3V$ | - | 30 | ns |

Additional Features for the XCFxxP

Internal Oscillator

The 8/16/32 Mbit XCFxxP Platform Flash PROMs include an optional internal oscillator which can be used to drive the CLKOUT and DATA pins on FPGA configuration interface. The internal oscillator can be enabled during device programming, and can be set to either the default frequency or to a slower frequency (**AC Characteristics Over Operating Conditions When Cascading**).

CLKOUT

The 8/16/32 Mbit XCFxxP Platform Flash PROMs include the programmable option to enable the CLKOUT signal which allows the PROM to provide a source synchronous clock aligned to the data on the configuration interface. The CLKOUT signal is derived from one of two clock sources: the CLK input pin or the internal oscillator. The input clock source is selected during the PROM programming sequence. Output data is available on the rising edge of CLKOUT.

The CLKOUT signal is enabled during programming, and is active when \overline{CE} is Low and OE/\overline{RESET} is High. When disabled, the CLKOUT pin is put into a high-impedance state and should be pulled High externally to provide a known state.

When cascading Platform Flash PROMs with CLKOUT enabled, after completing its data transfer, the first PROM disables CLKOUT and releases the \overline{CEO} pin enabling the next PROM in the PROM chain. The next PROM will begin driving the CLKOUT signal once that PROM is enabled and data is available for transfer.

During high-speed parallel configuration without compression, the FPGA drives the BUSY signal on the configuration interface. When BUSY is asserted High, the PROMs internal address counter stops incrementing, and the current data value is held on the data outputs. While BUSY is High, the PROM will continue driving the CLKOUT signal to the

FPGA, clocking the FPGAs configuration logic. When the FPGA deasserts BUSY, indicating that it is ready to receive additional configuration data, the PROM will begin driving new data onto the configuration interface.

Decompression

The 8/16/32 Mbit XCFxxP Platform Flash PROMs include a built-in data decompressor compatible with Xilinx advanced compression technology. Compressed Platform Flash PROM files are created from the target FPGA bitstream(s) using the iMPACT software. Only Slave Serial and Slave SelectMAP (parallel) configuration modes are supported for FPGA configuration when using a XCFxxP PROM programmed with a compressed bitstream. Compression rates will vary depending on several factors, including the target device family and the target design contents.

The decompression option is enabled during the PROM programming sequence. The PROM decompresses the stored data before driving both clock and data onto the FPGA's configuration interface. If Decompression is enabled, then the Platform Flash clock output pin (CLKOUT) must be used as the clock signal for the configuration interface, driving the target FPGA's configuration clock input pin (CCLK). Either the PROM's CLK input pin or the internal oscillator must be selected as the source for CLKOUT. Any target FPGA connected to the PROM must operate as slave in the configuration chain, with the configuration mode set to Slave Serial mode or Slave SelectMap (parallel) mode.

When decompression is enabled, the CLKOUT signal becomes a controlled clock output with a reduced maximum frequency and remains Low when decompressed data is not ready.

The BUSY input is automatically disabled when decompression is enabled.

Design Revisioning

Design Revisioning allows the user to create up to four unique design revisions on a single PROM or stored across

multiple cascaded PROMs. Design Revisioning is supported for the 8/16/32 Mbit XCFxxP Platform Flash PROMs in both serial and parallel modes. Design Revisioning can be used with compressed PROM files, and also when the CLKOUT feature is enabled. The PROM programming files along with the revision information files (.cfi) are created using the iMPACT software. The .cfi file is required to enable design revision programming in iMPACT.

A single design revision requires at least 8 Mbits of memory, but a larger design revision can span several devices. A single 32 Mbit PROM can store from one to four separate design revisions: one 32 Mbit design revision, two 16 Mbit design revisions, three 8 Mbit design revisions, or four 8 Mbit design revisions. A single 16 Mbit PROM can store up to two separate design revisions: one 16 Mbit design revision, two 8 Mbit design revisions. A single 8 Mbit PROM can store only one 8 Mbit design revision. Larger design revisions can be split over several cascaded PROMs.

During the PROM file creation, each design revision is assigned a revision number:

Revision 0 = '00'
Revision 1 = '01'
Revision 2 = '10'
Revision 3 = '11'

After programming the Platform Flash PROM, a particular design revision can be selected using the external REV_SEL[1:0] pins or using the internal programmable design revision control bits. The EN_EXT_SEL pin determines if the external pins or internal bits are used to select the design revision. When EN_EXT_SEL is Low, design revision selection is controlled by the external Revision Select pins, REV_SEL[1:0]. When EN_EXT_SEL is High, design revision selection is controlled by the internal programmable Revision Select control bits. During power up, the design revision selection inputs (pins or control bits) are sampled internally. After power up, the design revision selection inputs are sampled again after the rising edge of the CF pulse. The data from the selected design revision is then presented on the FPGA configuration interface.

Figure 7: Design Revision Storage Examples

PROM to FPGA Configuration Mode and Connections Summary

The FPGA's I/O, logical functions, and internal interconnections are established by the configuration data contained in the FPGAs bitstream. The bitstream is loaded into the FPGA either automatically upon power up, or on command, depending on the state of the FPGA's mode pins. Xilinx Platform Flash PROMs are designed to download directly to the FPGA configuration interface. FPGA configuration modes which are supported by the XCFxxS Platform Flash PROMs include: Master Serial and Slave Serial. FPGA configuration modes which are supported by the XCFxxP Platform Flash PROMs include: Master Serial, Slave Serial, Master SelectMAP, and Slave SelectMAP. Below is a short summary of the supported FPGA configuration modes. See the respective FPGA data sheet for device configuration details, including which configuration modes are supported by the targeted FPGA device.

FPGA Master Serial Mode

In Master Serial mode, the FPGA automatically loads the configuration bitstream in bit-serial form from external memory synchronized by the configuration clock (CCLK) generated by the FPGA. Upon power-up or reconfiguration, the FPGA's mode select pins are used to select the Master Serial configuration mode. Master Serial Mode provides a simple configuration interface. Only a serial data line, a clock line, and two control lines (INIT and DONE) are required to configure an FPGA. Data from the PROM is read out sequentially on a single data line (DIN), accessed via the PROM's internal address counter which is incremented on every valid rising edge of CCLK. The serial bitstream data must be setup at the FPGAs DIN input pin a short time before each rising edge of the FPGA's internally generated CCLK signal.

Typically, a wide range of frequencies can be selected for the FPGA's internally generated CCLK which always starts at a slow default frequency. The FPGAs bitstream contains configuration bits which can switch CCLK to a higher frequency for the remainder of the Master Serial configuration sequence. The desired CCLK frequency is selected during bitstream generation.

Connecting the FPGA device to the configuration PROM for Master Serial Configuration Mode (Figure 8):

- The DATA output of the PROM(s) drive the DIN input of the lead FPGA device.
- The Master FPGA CCLK output drives the CLK input(s) of the PROM(s)
- The \overline{CEO} output of a PROM drives the \overline{CE} input of the next PROM in a daisy chain (if any).
- The OE/ \overline{RESET} pins of all PROMs are connected to the INIT_B pins of all FPGA devices. This connection assures that the PROM address counter is reset before the start of any (re)configuration.
- The PROM \overline{CE} input can be driven from the DONE pin.

The \overline{CE} input of the first (or only) PROM can be driven by the DONE output of all target FPGA devices, provided that DONE is not permanently grounded. \overline{CE} can also be permanently tied Low, but this keeps the DATA output active and causes an unnecessary I_{CC} active supply current (**DC Characteristics Over Operating Conditions**).

- The PROM \overline{CF} pin is typically connected to the FPGA's PROG_B (or PROGRAM) input.

FPGA Slave Serial Mode

In Slave Serial mode, the FPGA loads the configuration bitstream in bit-serial form from external memory synchronized by an externally supplied clock. Upon power-up or reconfiguration, the FPGA's mode select pins are used to select the Slave Serial configuration mode. Slave Serial Mode provides a simple configuration interface. Only a serial data line, a clock line, and two control lines (INIT and DONE) are required to configure an FPGA. Data from the PROM is read out sequentially on a single data line (DIN), accessed via the PROM's internal address counter which is incremented on every valid rising edge of CCLK. The serial bitstream data must be setup at the FPGAs DIN input pin a short time before each rising edge of the externally provided CCLK.

Connecting the FPGA device to the configuration PROM for Slave Serial Configuration Mode (Figure 9):

- The DATA output of the PROM(s) drive the DIN input of the lead FPGA device.
- The PROM CLKOUT (for XCFxxP only) or an external clock source drives the FPGA's CCLK input.
- The \overline{CEO} output of a PROM drives the \overline{CE} input of the next PROM in a daisy chain (if any).
- The OE/ \overline{RESET} pins of all PROMs are connected to the INIT_B (or INIT) pins of all FPGA devices. This connection assures that the PROM address counter is reset before the start of any (re)configuration.
- The PROM \overline{CE} input can be driven from the DONE pin. The \overline{CE} input of the first (or only) PROM can be driven by the DONE output of all target FPGA devices, provided that DONE is not permanently grounded. \overline{CE} can also be permanently tied Low, but this keeps the DATA output active and causes an unnecessary I_{CC} active supply current (**DC Characteristics Over Operating Conditions**).
- The PROM \overline{CF} pin is typically connected to the FPGA's PROG_B (or PROGRAM) input.

Serial Daisy Chain

Multiple FPGAs can be daisy-chained for serial configuration from a single source. After a particular FPGA has been configured, the data for the next device is routed internally

to the FPGAs DOUT pin. Typically the data on the DOUT pin changes on the falling edge of CCLK, although for some devices the DOUT pin changes on the rising edge of CCLK. Consult the respective device data sheets for detailed information on a particular FPGA device. For clocking the daisy-chained configuration, either the first FPGA in the chain can be set to Master Serial, generating the CCLK, with the remaining devices set to Slave Serial (**Figure 10**), or all the FPGA devices can be set to Slave Serial and an externally generated clock can be used to drive the FPGA's configuration interface.

FPGA Master SelectMAP (Parallel) Mode⁽¹⁾

In Master SelectMAP mode, byte-wide data is written into the FPGA, typically with a BUSY flag controlling the flow of data, synchronized by the configuration clock (CCLK) generated by the FPGA. Upon power-up or reconfiguration, the FPGA's mode select pins are used to select the Master SelectMAP configuration mode. The configuration interface typically requires a parallel data bus, a clock line, and two control lines (INIT and DONE). In addition, the FPGAs Chip Select, Write, and BUSY pins must be correctly controlled to enable SelectMAP configuration. The configuration data is read from the PROM byte by byte on pins [D0..D7], accessed via the PROM's internal address counter which is incremented on every valid rising edge of CCLK. The bitstream data must be setup at the FPGAs [D0..D7] input pins a short time before each rising edge of the FPGA's internally generated CCLK signal. If BUSY is asserted (High) by the FPGA, the configuration data must be held until BUSY goes Low. An external data source or external pull-down resistors must be used to enable the FPGA's active Low Chip Select (\overline{CS} or CS_B) and Write (\overline{WRITE} or RDWR_B) signals to enable the FPGA's SelectMAP configuration process.

The Master SelectMAP configuration interface is clocked by the FPGA's internal oscillator. Typically, a wide range of frequencies can be selected for the internally generated CCLK which always starts at a slow default frequency. The FPGAs bitstream contains configuration bits which can switch CCLK to a higher frequency for the remainder of the Master SelectMAP configuration sequence. The desired CCLK frequency is selected during bitstream generation.

Connecting the FPGA device to the configuration PROM for Master SelectMAP (Parallel) Configuration Mode (**Figure 11**):

- The DATA outputs of the PROM(s) drive the [D0..D7] input of the lead FPGA device.
- The Master FPGA CCLK output drives the CLK input(s) of the PROM(s)

- The \overline{CEO} output of a PROM drives the \overline{CE} input of the next PROM in a daisy chain (if any).
- The OE/ \overline{RESET} pins of all PROMs are connected to the INIT_B pins of all FPGA devices. This connection assures that the PROM address counter is reset before the start of any (re)configuration.
- The PROM \overline{CE} input can be driven from the DONE pin. The \overline{CE} input of the first (or only) PROM can be driven by the DONE output of all target FPGA devices, provided that DONE is not permanently grounded. \overline{CE} can also be permanently tied Low, but this keeps the DATA output active and causes an unnecessary I_{CC} active supply current (**DC Characteristics Over Operating Conditions**).
- For high-frequency parallel configuration, the BUSY pins of all PROMs are connected to the FPGA's BUSY output. This connection assures that the PROM is only enabled when the FPGA is ready for the next configuration data byte.
- The PROM \overline{CF} pin is typically connected to the FPGA's PROG_B (or PROGRAM) input.

FPGA Slave SelectMAP (Parallel) Mode⁽²⁾

In Slave SelectMAP mode, byte-wide data is written into the FPGA, typically with a BUSY flag controlling the flow of data, synchronized by an externally supplied configuration clock (CCLK). Upon power-up or reconfiguration, the FPGA's mode select pins are used to select the Slave SelectMAP configuration mode. The configuration interface typically requires a parallel data bus, a clock line, and two control lines (INIT and DONE). In addition, the FPGAs Chip Select, Write, and BUSY pins must be correctly controlled to enable SelectMAP configuration. The configuration data is read from the PROM byte by byte on pins [D0..D7], accessed via the PROM's internal address counter which is incremented on every valid rising edge of CCLK. The bitstream data must be setup at the FPGAs [D0..D7] input pins a short time before each rising edge of the provided CCLK. If BUSY is asserted (High) by the FPGA, the configuration data must be held until BUSY goes Low. An external data source or external pull-down resistors must be used to enable the FPGA's active Low Chip Select (\overline{CS} or CS_B) and Write (\overline{WRITE} or RDWR_B) signals to enable the FPGA's SelectMAP configuration process.

After configuration, the pins of the SelectMAP port can be used as additional user I/O. Alternatively, the port can be retained using the persist option.

Connecting the FPGA device to the configuration PROM for Slave SelectMAP (Parallel) Configuration Mode (**Figure 12**):

1. The Master SelectMAP (Parallel) FPGA configuration mode is supported only by the XCFxxP Platform Flash PROM. This mode is not supported by the XCFxxS Platform Flash PROM.

2. The Slave SelectMAP (Parallel) FPGA configuration mode is supported only by the XCFxxP Platform Flash PROMs. This mode is not supported by the XCFxxS Platform Flash PROM.

- The DATA outputs of the PROM(s) drives the [D0..D7] inputs of the lead FPGA device.
- The PROM CLKOUT (for XCFxxP only) or an external clock source drives the FPGA's CCLK input
- The \overline{CEO} output of a PROM drives the \overline{CE} input of the next PROM in a daisy chain (if any).
- The OE/ \overline{RESET} pins of all PROMs are connected to the INIT_B pins of all FPGA devices. This connection assures that the PROM address counter is reset before the start of any (re)configuration.
- The PROM \overline{CE} input can be driven from the DONE pin. The \overline{CE} input of the first (or only) PROM can be driven by the DONE output of all target FPGA devices, provided that DONE is not permanently grounded. \overline{CE} can also be permanently tied Low, but this keeps the DATA output active and causes an unnecessary I_{CC} active supply current (**DC Characteristics Over Operating Conditions**).
- For high-frequency parallel configuration, the BUSY pins of all PROMs are connected to the FPGA's BUSY output. This connection assures that the PROM is only enabled when the FPGA is ready for the next configuration data byte.
- The PROM \overline{CF} pin is typically connected to the FPGA's PROG_B (or PROGRAM) input.

FPGA SelectMAP (Parallel) Device Chaining⁽¹⁾

Multiple Virtex-II FPGAs can be configured using the SelectMAP mode, and be made to start-up simultaneously. To configure multiple devices in this way, wire the individual CCLK, DONE, INIT, Data ([D0..D7]), Write (WRITE or RDWR_B), and BUSY pins of all the devices in parallel. If all devices are to be configured with the same bitstream, read-back is not being used, and the CCLK frequency selected does not require the use of the BUSY signal, the CS_B pins can be connected to a common line so all of the devices are configured simultaneously (Figure 13).

With additional control logic, the individual devices can be loaded separately by asserting the CS_B pin of each device in turn and then enabling the appropriate configuration data. The PROM can also store the individual bitstreams for each FPGA for SelectMAP configuration in separate design revisions. When design revisioning is utilized, additional control logic can be used to select the appropriate bitstream by asserting the $\overline{EN_EXT_SEL}$ pin, and using the REV_SEL[1:0] pins to select the required bitstream, while asserting the CS_B pin for the FPGA the bitstream is targeting (Figure 14).

1. The SelectMAP (Parallel) FPGA configuration modes are supported only by the XCFxxP Platform Flash PROM. These modes are not supported by the XCFxxS Platform Flash PROM.

For clocking the parallel configuration chain, either the first FPGA in the chain can be set to Master SelectMAP, generating the CCLK, with the remaining devices set to Slave SelectMAP, or all the FPGA devices can be set to Slave SelectMAP and an externally generated clock can be used to drive the configuration interface. Again, the respective device data sheets should be consulted for detailed information on a particular FPGA device, including which configuration modes are supported by the targeted FPGA device.

Cascading Configuration PROMs

When configuring multiple FPGAs in a serial daisy chain, configuring multiple FPGAs in a SelectMAP parallel chain, or configuring a single FPGA requiring a larger configuration bitstream, cascaded PROMs provide additional memory (Figure 10, Figure 13, Figure 14, and Figure 15). Multiple Platform Flash PROMs can be concatenated by using the \overline{CEO} output to drive the \overline{CE} input of the downstream device. The clock signal and the data outputs of all Platform Flash PROMs in the chain are interconnected. After the last data from the first PROM is read, the first PROM asserts its \overline{CEO} output Low and drives its outputs to a high-impedance state. The second PROM recognizes the Low level on its \overline{CE} input and immediately enables its outputs.

After configuration is complete, address counters of all cascaded PROMs are reset if the PROM OE/ \overline{RESET} pin goes Low or \overline{CE} goes High.

When utilizing the advanced features for the XCFxxP Platform Flash PROM, including the clock output (CLKOUT) option, decompression option, or design revisioning, programming files which span cascaded PROM devices can only be created for cascaded chains containing only XCFxxP PROMs. If the advanced features are not used, then cascaded PROM chains can contain both XCFxxP and XCFxxS PROMs.

Initiating FPGA Configuration

The options for initiating FPGA configuration via the Platform Flash PROM include:

1. Automatic configuration on power up
2. Applying an external PROG_B (or PROGRAM) pulse
3. Applying the JTAG CONFIG instruction

Following the FPGA's power-on sequence or the assertion of the PROG_B (or PROGRAM) pin the FPGAs configuration memory is cleared, the configuration mode is selected, and the FPGA is ready to accept a new configuration bitstream. The FPGA's PROG_B pin can be controlled by an external source, or alternatively, the Platform Flash PROMs incorporate a \overline{CF} pin that can be tied to the FPGAs PROG_B pin. Executing the CONFIG instruction through JTAG pulses the \overline{CF} output Low once for 300-500 ns, resetting the FPGA and initiating configuration. The iMPACT soft-

ware can issue the JTAG CONFIG command to initiate FPGA configuration by setting the "Load FPGA" option.

When using the XCFxxP Platform Flash PROM with design revisioning enabled, the \overline{CF} pin should always be connected to the PROG_B (or PROGRAM) pin on the FPGA to ensure that the current design revision selection is sampled when

the FPGA is reset. The XCFxxP PROM samples the current design revision selection from the external REV_SEL pins or the internal programmable Revision Select bits on the rising edge of \overline{CF} . When the JTAG CONFIG command is executed, the XCFxxP will sample the new design revision before initiating the FPGA configuration sequence.

ds123_18_110303

Figure 15: Configuring Multiple Devices with Design Revisioning in Slave SelectMAP Mode

Reset and Power-On Reset Activation

At power up, the device requires the V_{CCINT} power supply to monotonically rise to the nominal operating voltage within the specified V_{CCINT} rise time. If the power supply cannot meet this requirement, then the device might not perform power-on reset properly. During the power-up sequence, OE/\overline{RESET} is held Low by the PROM. Once the required supplies have reached their respective POR (Power On Reset) thresholds, the OE/\overline{RESET} release is delayed (T_{OER} minimum) to allow more margin for the power supplies to stabilize before initiating configuration. The OE/\overline{RESET} pin is connected to an external pull-up resistor and also to the target FPGA's INIT pin. For systems utilizing slow-rising power supplies, an additional power monitoring circuit can be used to delay the target configuration until the system power reaches minimum operating voltages by holding the OE/\overline{RESET} pin Low. When OE/\overline{RESET} is released, the FPGA's INIT pin is pulled High allowing the FPGA's configuration sequence to begin. If the power drops below the

power-down threshold (V_{CCPD}), the PROM resets and OE/\overline{RESET} is again held Low until the after the POR threshold is reached. OE/\overline{RESET} polarity is not programmable. These power-up requirements are shown graphically in Figure 16.

For a fully powered Platform Flash PROM, a reset occurs whenever OE/\overline{RESET} is asserted (Low) or \overline{CE} is deasserted (High). The address counter is reset, \overline{CEO} is driven High, and the remaining outputs are placed in a high-impedance state.

Notes:

1. The XCFxxS PROM only requires V_{CCINT} to rise above its POR threshold before releasing OE/\overline{RESET} .
2. The XCFxxP PROM requires both V_{CCINT} to rise above its POR threshold and for V_{CCO} to reach the recommended operating voltage level before releasing OE/\overline{RESET} .

Figure 16: Platform Flash PROM Power-Up Requirements

I/O Input Voltage Tolerance and Power Sequencing

The I/Os on each re-programmable Platform Flash PROM are fully 3.3V-tolerant. This allows 3V CMOS signals to connect directly to the inputs without damage. The V_{CCINT} power can be applied before or after 3V CMOS signals are applied to the I/Os. The core power supply (V_{CCINT}), JTAG pin power supply (V_{CCJ}), and output power supply (V_{CCO}) can be applied in any order. The PROM should not be partially powered, with one supply left unpowered while another supply is fully powered. Failure to power the PROM correctly may result in damage to the device.

Additionally, for the XCFxxS PROM only, when V_{CCO} is supplied at 2.5V or 3.3V and V_{CCINT} is supplied at 3.3V, the I/Os

are 5V-tolerant. This allows 5V CMOS signals to connect directly to the inputs on a powered XCFxxS PROM without damage.

Standby Mode

The PROM enters a low-power standby mode whenever \overline{CE} is deasserted (High). In standby mode, the address counter is reset, \overline{CEO} is driven High, and the remaining outputs are placed in a high-impedance state regardless of the state of the OE/\overline{RESET} input. For the device to remain in the low-power standby mode, the JTAG pins TMS, TDI, and TDO must not be pulled Low, and TCK must be stopped (High or Low).

Table 9: Truth Table for XCFxxS PROM Control Inputs

| Control Inputs | | Internal Address | Outputs | | |
|------------------|------|---|---------|------|---------|
| OE/RESET | CE | | DATA | CEO | ICC |
| High | Low | If address < TC ⁽²⁾ : increment | Active | High | Active |
| | | If address = TC ⁽²⁾ : don't change | High-Z | Low | Reduced |
| Low | Low | Held reset | High-Z | High | Active |
| X ⁽¹⁾ | High | Held reset | High-Z | High | Standby |

Notes:

1. X = don't care.
2. TC = Terminal Count = highest address value. TC + 1 = address 0.

Table 10: Truth Table for XCFxxP PROM Control Inputs

| Control Inputs | | | Internal Address | Outputs | | | |
|------------------|------|------|---|----------------------|------|--------|---------|
| OE/RESET | CE | BUSY | | DATA | CEO | CLKOUT | ICC |
| High | Low | Low | If address < TC ⁽²⁾ and address < EA ⁽³⁾ : increment | Active | High | Active | Active |
| | | | If address < TC ⁽²⁾ and address = EA ⁽³⁾ : don't change | High-Z | High | High-Z | Reduced |
| | | | Else if address = TC ⁽²⁾ : don't change | High-Z | Low | High-Z | Reduced |
| High | Low | High | Unchanged | Active and Unchanged | High | Active | Active |
| Low | Low | X | Held reset ⁽⁴⁾ | High-Z | High | High-Z | Active |
| X ⁽¹⁾ | High | X | Held reset ⁽⁴⁾ | High-Z | High | High-Z | Standby |

Notes:

1. X = don't care.
2. TC = Terminal Count = highest address value.
3. For the XCFxxP with Design Revisioning enabled, EA = end address (last address in the selected design revision).
4. For the XCFxxP with Design Revisioning enabled, Held Reset = address reset to the beginning address of the selected bank. If Design Revisioning is not enabled, then Held Reset = address reset to address 0.

Absolute Maximum Ratings

| Symbol | Description | XCF01S, XCF02S, XCF04S | XCF08P, XCF16P, XCF32P | Units |
|-----------------|--|---------------------------|---------------------------|-------|
| V_{CCINT} | Internal supply voltage relative to GND | −0.5 to +4.0 | −0.5 to +2.7 | V |
| V_{CCO} | I/O supply voltage relative to GND | −0.5 to +4.0 | −0.5 to +4.0 | V |
| V_{CCJ} | JTAG I/O supply voltage relative to GND | −0.5 to +4.0 | −0.5 to +4.0 | V |
| V_{IN} | Input voltage with respect to GND | $V_{CCO} < 2.5V$ | −0.5 to $V_{CCO} + 0.5$ | V |
| | | $V_{CCO} \geq 2.5V$ | −0.5 to $V_{CCO} + 0.5$ | V |
| V_{TS} | Voltage applied to High-Z output | $V_{CCO} < 2.5V$ | −0.5 to $V_{CCO} + 0.5$ | V |
| | | $V_{CCO} \geq 2.5V$ | −0.5 to $V_{CCO} + 0.5$ | V |
| T_{STG} | Storage temperature (ambient) | −65 to +150 | −65 to +150 | °C |
| $T_{SOL}^{(3)}$ | Maximum soldering temperature (10s @ 1/16 in.) | +220 | +220 | °C |
| T_J | Junction temperature | +125 | +125 | °C |

Notes:

- Maximum DC undershoot below GND must be limited to either 0.5V or 10 mA, whichever is easier to achieve. During transitions, the device pins can undershoot to −2.0V or overshoot to +7.0V, provided this over- or undershoot lasts less than 10 ns and with the forcing current being limited to 200 mA.
- Stresses beyond those listed under Absolute Maximum Ratings might cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those listed under Operating Conditions is not implied. Exposure to Absolute Maximum Ratings conditions for extended periods of time adversely affects device reliability.
- For soldering guidelines, see the information on "Packaging and Thermal Characteristics" at www.xilinx.com.

Supply Voltage Requirements for Power-On Reset and Power-Down

| Symbol | Description | XCF01S, XCF02S, XCF04S | | XCF08P, XCF16P, XCF32P | | Units |
|-------------|--|---------------------------|-----|---------------------------|-----|-------|
| | | Min | Max | Min | Max | |
| V_{CCPOR} | POR threshold for the V_{CCINT} supply | 1 | - | TBD | - | V |
| T_{OER} | OE/RESET release delay following POR ⁽⁴⁾ | 0 | 1 | 0 | TBD | ms |
| T_{VCC} | V_{CCINT} rise time from 0V to nominal voltage | 0.2 | 50 | 0.2 | 50 | ms |
| T_{RST} | Time required to trigger a device reset when the V_{CCINT} supply drops below the maximum V_{CCPD} threshold | 10 | - | 10 | - | ms |
| V_{CCPD} | Power-down threshold for V_{CCINT} supply | - | 1 | - | TBD | V |

Notes:

- V_{CCINT} , V_{CCO} , and V_{CCJ} supplies may be applied in any order.
- At power up, the device requires the V_{CCINT} power supply to monotonically rise to the nominal operating voltage within the specified T_{VCC} rise time. If the power supply cannot meet this requirement, then the device might not perform power-on-reset properly. See [Figure 16, page 21](#).
- If the V_{CCINT} and V_{CCO} supplies do not reach their respective recommended operating conditions before the OE/RESET pin is released, then the configuration data from the PROM will not be available at the recommended threshold levels. The configuration sequence must be delayed until both V_{CCINT} and V_{CCO} have reached their recommended operating conditions.

Recommended Operating Conditions

| Symbol | Description | | XCF01S, XCF02S, XCF04S | | XCF08P, XCF16P, XCF32P | | Units |
|------------------------------------|-----------------------------------|------------------------|---------------------------|----------------------|---------------------------|----------------------|-------|
| | | | Min | Max | Min | Max | |
| V _{CCINT} | Internal voltage supply | | 3.0 | 3.6 | 1.65 | 2.0 | V |
| V _{CCO} /V _{CCJ} | Supply voltage for output drivers | 3.3V Operation | 3.0 | 3.6 | 3.0 | 3.6 | V |
| | | 2.5V Operation | 2.3 | 2.7 | 2.3 | 2.7 | V |
| | | 1.8V Operation | 1.7 | 2.0 | 1.7 | 2.0 | V |
| | | 1.5V Operation | - | - | TBD | TBD | V |
| V _{IL} | Low-level input voltage | 2.5V or 3.3V Operation | 0 | 0.8 | 0 | 0.8 | V |
| | | 1.8V Operation | 0 | 20% V _{CCO} | 0 | 20% V _{CCO} | V |
| V _{IH} | High-level input voltage | 2.5V or 3.3V Operation | 2.0 | 5.5 | 2.0 | 3.6 | V |
| | | 1.8V Operation | 70% V _{CCO} | 3.6 | 70% V _{CCO} | 3.6 | V |
| V _O | Output voltage | | 0 | V _{CCO} | 0 | V _{CCO} | V |
| T _A | Operating ambient temperature | | -40 | 85 | -40 | 85 | °C |

Quality and Reliability Characteristics

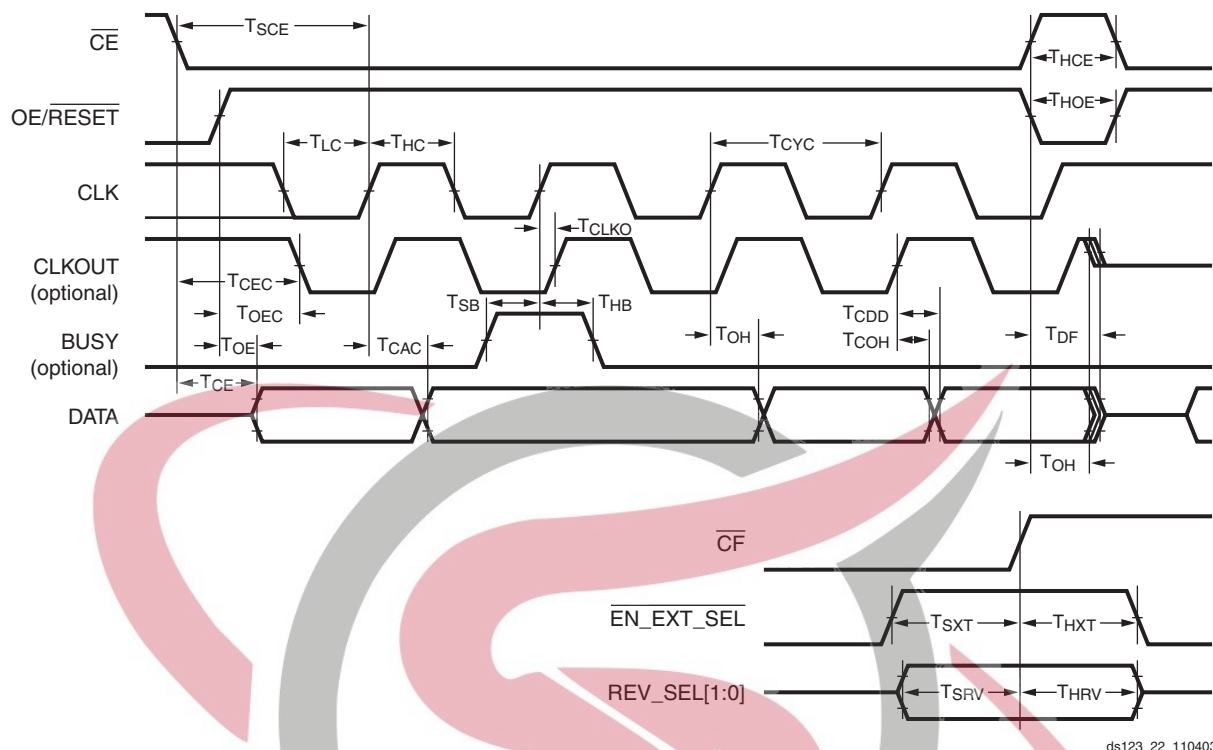

| Symbol | Description | Min | Max | Units |
|------------------|----------------------------------|--------|-----|--------|
| T _{DR} | Data retention | 20 | - | Years |
| N _{PE} | Program/erase cycles (Endurance) | 20,000 | - | Cycles |
| V _{ESD} | Electrostatic discharge (ESD) | 2,000 | - | Volts |

| | CLKOUT alternate (slower) frequency with compression | - | - | TBD | TBD | ns |

Notes:

1. AC test load = 50 pF.
2. Float delays are measured with 5 pF AC loads. Transition is measured at ± 200 mV from steady state active levels.
3. Guaranteed by design, not tested.
4. All AC parameters are measured with V_{IL} = 0.0V and V_{IH} = 3.0V.
5. If T_{HCE} High < 2 μ s, T_{CE} = 2 μ s.
6. If T_{HOE} Low < 2 μ s, T_{OE} = 2 μ s.
7. Minimum possible T_{CYC}. Actual T_{CYC} = T_{CAC} + FPGA data setup time. If FPGA data setup time = 15 ns, actual T_{CYC} = 15 ns + 15 ns = 30 ns.

| | CLKOUT to output float delay when V _{CCO} = 1.8V | - | - | TBD | TBD | ns |

Notes:

1. AC test load = 50 pF.
2. Float delays are measured with 5 pF AC loads. Transition is measured at ± 200 mV from steady state active levels.
3. Guaranteed by design, not tested.
4. All AC parameters are measured with V_{IL} = 0.0V and V_{IH} = 3.0V.
5. For cascaded PROMs minimum, T_{CYC} = T_{OCK} + FPGA Data setup time.

Pinouts and Pin Descriptions

The XCFxxS Platform Flash PROM is available in the VO20 package. The XCFxxP Platform Flash PROM is available in the VO48 and FS48 packages. This section includes:

- Table 11, **XCFxxS Pin Names and Descriptions**, page 30
- Figure 17, **VO20 Pinout Diagram (Top View) with Pin Names**, page 31
- Table 12, **XCFxxP Pin Names and Descriptions**, page 32
- Figure 18, **VO48 Pinout Diagram (Top View) with Pin Names**, page 34
- Figure 19, **FS48 Pinout Diagram (Top View)**, page 34
- Table 13, **FS48 Pin Number/Name Reference**, page 35

Notes:

1. VO20 denotes a 20-pin (TSSOP) Plastic Thin Shrink Small Outline Package
2. VO48 denotes a 48-pin (TSOP) Plastic Thin Small Outline Package.
3. FS48 denotes a 48-pin (TFBGA) Plastic Thin Fine Pitch Ball Grid Array (0.8 mm pitch).

XCFxxS Pinouts and Pin Descriptions

Table 11 provides a list of the pin names and descriptions for the XCFxxS 20-pin VO20 package.

Table 11: XCFxxS Pin Names and Descriptions

| Pin Name | Boundary Scan Order | Boundary Scan Function | Pin Description | 20-pin TSSOP (VO20) |
|-----------------------|---------------------|------------------------|---|---------------------|
| D0 | 4 | Data Out | D0 is the DATA output pin to provide data for configuring an FPGA in serial mode. The D0 output is set to a high-impedance state during ISPEN (when not clamped). | 1 |
| | 3 | Output Enable | | |
| CLK | 0 | Data In | Configuration Clock Input. Each rising edge on the CLK input increments the internal address counter if the CLK input is selected, \overline{CE} is Low, and OE/\overline{RESET} is High. | 3 |
| OE/\overline{RESET} | 20 | Data In | Output Enable/Reset (Open-Drain I/O). When Low, this input holds the address counter reset and the DATA output is in a high-impedance state. This is a bidirectional open-drain pin that is held Low while the PROM is reset. Polarity is not programmable. | 8 |
| | 19 | Data Out | | |
| | 18 | Output Enable | | |
| \overline{CE} | 15 | Data In | Chip Enable Input. When \overline{CE} is High, the device is put into low-power standby mode, the address counter is reset, and the DATA pins are put in a high-impedance state. | 10 |
| \overline{CF} | 22 | Data Out | Configuration Pulse (Open-Drain Output). Allows JTAG CONFIG instruction to initiate FPGA configuration without powering down FPGA. This is an open-drain output that is pulsed Low by the JTAG CONFIG command. | 7 |
| | 21 | Output Enable | | |
| \overline{CEO} | 12 | Data Out | Chip Enable Output. Chip Enable Output (\overline{CEO}) is connected to the \overline{CE} input of the next PROM in the chain. This output is Low when \overline{CE} is Low and OE/\overline{RESET} input is High, AND the internal address counter has been incremented beyond its Terminal Count (TC) value. \overline{CEO} returns to High when OE/\overline{RESET} goes Low or \overline{CE} goes High. | 13 |
| | 11 | Output Enable | | |
| TMS | | Mode Select | JTAG Mode Select Input. The state of TMS on the rising edge of TCK determines the state transitions at the Test Access Port (TAP) controller. TMS has an internal 50K Ω resistive pull-up to V_{CCJ} to provide a logic "1" to the device if the pin is not driven. | 5 |

Table 11: XCFxxS Pin Names and Descriptions (Continued)

| Pin Name | Boundary Scan Order | Boundary Scan Function | Pin Description | 20-pin TSSOP (VO20) |
|----------|---------------------|------------------------|---|----------------------|
| TCK | | Clock | JTAG Clock Input. This pin is the JTAG test clock. It sequences the TAP controller and all the JTAG test and programming electronics. | 6 |
| TDI | | Data In | JTAG Serial Data Input. This pin is the serial input to all JTAG instruction and data registers. TDI has an internal 50K Ω resistive pull-up to V _{CCJ} to provide a logic "1" to the device if the pin is not driven. | 4 |
| TDO | | Data Out | JTAG Serial Data Output. This pin is the serial output for all JTAG instruction and data registers. TDO has an internal 50K Ω resistive pull-up to V _{CCJ} to provide a logic "1" to the system if the pin is not driven. | 17 |
| VCCINT | | | +3.3V Supply. Positive 3.3V supply voltage for internal logic. | 18 |
| VCCO | | | +3.3V, 2.5V, or 1.8V I/O Supply. Positive 3.3V, 2.5V, or 1.8V supply voltage connected to the output voltage drivers and input buffers. | 19 |
| VCCJ | | | +3.3V, 2.5V, or 1.8V JTAG I/O Supply. Positive 3.3V, 2.5V, or 1.8V supply voltage connected to the TDO output voltage driver and TCK, TMS, and TDI input buffers. | 20 |
| GND | | | Ground | 11 |
| DNC | | | Do not connect. (These pins must be left unconnected.) | 2, 9, 12, 14, 15, 16 |

XCFxxS Pinout Diagram

Figure 17: VO20 Pinout Diagram (Top View) with Pin Names

XCFxxP Pinouts and Pin Descriptions

Table 12 provides a list of the pin names and descriptions for the XCFxxP 48-pin VO48 and 48-pin FS48 packages.

Table 12: XCFxxP Pin Names and Descriptions

| Pin Name | Boundary Scan Order | Boundary Scan Function | Pin Description | 48-pin TSOP (VO48) | 48-pin TFBGA (FS48) |
|-----------------|---------------------|------------------------|--|--------------------|---------------------|
| D0 | 28 | Data Out | <p>D0 is the DATA output pin to provide data for configuring an FPGA in serial mode.</p> <p>D0-D7 are the DATA output pins to provide parallel data for configuring a Xilinx FPGA in SelectMap (parallel) mode.</p> <p>The D0 output is set to a high-impedance state during ISPEN (when not clamped).</p> <p>The D1-D7 outputs are set to a high-impedance state during ISPEN (when not clamped) and when serial mode is selected for configuration. The D1-D7 pins can be left unconnected when the PROM is used in serial mode.</p> | 28 | H6 |
| | 27 | Output Enable | | | |
| D1 | 26 | Data Out | | 29 | H5 |
| | 25 | Output Enable | | | |
| D2 | 24 | Data Out | | 32 | E5 |
| | 23 | Output Enable | | | |
| D3 | 22 | Data Out | | 33 | D5 |
| | 21 | Output Enable | | | |
| D4 | 20 | Data Out | | 43 | C5 |
| | 19 | Output Enable | | | |
| D5 | 18 | Data Out | | 44 | B5 |
| | 17 | Output Enable | | | |
| D6 | 16 | Data Out | | 47 | A5 |
| | 15 | Output Enable | | | |
| D7 | 14 | Data Out | | 48 | A6 |
| | 13 | Output Enable | | | |
| CLK | 01 | Data In | Configuration Clock Input. An internal programmable control bit selects between the internal oscillator and the CLK input pin as the clock source to control the configuration sequence. Each rising edge on the CLK input increments the internal address counter if the CLK input is selected, \overline{CE} is Low, and OE/RESET is High. | 12 | B3 |
| OE/RESET | 04 | Data In | Output Enable/Reset (Open-Drain I/O). | 11 | A3 |
| | 03 | Data Out | When Low, this input holds the address counter reset and the DATA and CLKOUT outputs are placed in a high-impedance state. This is a bidirectional open-drain pin that is held Low while the PROM is reset. Polarity is not programmable. | | |
| | 02 | Output Enable | | | |
| \overline{CE} | 00 | Data In | Chip Enable Input. When \overline{CE} is High, the device is put into low-power standby mode, the address counter is reset, and the DATA and CLKOUT outputs are placed in a high-impedance state. | 13 | B4 |
| \overline{CF} | 11 | Data In | Configuration Pulse (Open-Drain I/O). As an output, this pin allows JTAG CONFIG instruction to initiate FPGA configuration without powering down the FPGA. This is an open-drain signal that is pulsed Low by the JTAG CONFIG command. As an input, when Low, this signal enables the device to sample the current design revision selection. | 6 | D1 |
| | 10 | Data Out | | | |
| | 09 | Output Enable | | | |

Table 12: XCFxxP Pin Names and Descriptions

| Pin Name | Boundary Scan Order | Boundary Scan Function | Pin Description | 48-pin TSOP (VO48) | 48-pin TFBGA (FS48) |
|---------------------------|---------------------|------------------------|--|--------------------|---------------------|
| \overline{CEO} | 06 | Data Out | Chip Enable Output. Chip Enable Output (\overline{CEO}) is connected to the \overline{CE} input of the next PROM in the chain. This output is Low when \overline{CE} is Low and OE/ \overline{RESET} input is High, AND the internal address counter has been incremented beyond its Terminal Count (TC) value. \overline{CEO} returns to High when OE/ \overline{RESET} goes Low or \overline{CE} goes High. | 10 | D2 |
| | 05 | Output Enable | | | |
| $\overline{EN_EXT_SEL}$ | 31 | Data In | Enable External Selection Input. When this pin is Low, design revision selection is controlled by the Revision Select pins. When this pin is High, design revision selection is controlled by the internal programmable Revision Select control bits. $\overline{EN_EXT_SEL}$ has an internal 50K Ω resistive pull-up to V_{CCO} to provide a logic "1" to the device if the pin is not driven. | 25 | H4 |
| REV_SELO | 30 | Data In | Revision Select[1:0] Inputs. When the $\overline{EN_EXT_SEL}$ is Low, the Revision Select pins are used to select the design revision to be enabled, overriding the internal programmable Revision Select control bits. The Revision Select[1:0] inputs have an internal 50K Ω resistive pull-up to V_{CCO} to provide a logic "1" to the device if the pins are not driven. | 26 | G3 |
| REV_SEL1 | 29 | Data In | | 27 | G4 |
| BUSY | 12 | Data In | Busy Input. The BUSY input is enabled when parallel mode is selected for configuration. When BUSY is High, the internal address counter stops incrementing and the current data remains on the data pins. On the first rising edge of CLK after BUSY transitions from High to Low, the data for the next address is driven on the data pins. When serial mode or decompression is enabled during device programming, the BUSY input is disabled. BUSY has an internal 50K Ω resistive pull-down to GND to provide a logic "0" to the device if the pin is not driven. | 5 | C1 |
| CLKOUT | 08 | Data Out | Configuration Clock Output. An internal Programmable control bit enables the CLKOUT signal which is sourced from either the internal oscillator or the CLK input pin. Each rising edge on the selected clock source increments the internal address counter if data is available, \overline{CE} is Low, and OE/ \overline{RESET} is High. Output data is available on the rising edge of CLKOUT. CLKOUT remains Low when data is not ready. When CLKOUT is not enabled, the CLKOUT pin is put into a high-impedance state. | 9 | C2 |
| | 07 | Output Enable | | | |
| TMS | | Mode Select | JTAG Mode Select Input. The state of TMS on the rising edge of TCK determines the state transitions at the Test Access Port (TAP) controller. TMS has an internal 50K Ω resistive pull-up to V_{CCJ} to provide a logic "1" to the device if the pin is not driven. | 21 | E2 |
| TCK | | Clock | JTAG Clock Input. This pin is the JTAG test clock. It sequences the TAP controller and all the JTAG test and programming electronics. | 20 | H3 |
| TDI | | Data In | JTAG Serial Data Input. This pin is the serial input to all JTAG instruction and data registers. TDI has an internal 50K Ω resistive pull-up to V_{CCJ} to provide a logic "1" to the device if the pin is not driven. | 19 | G1 |

Table 12: XCFxxP Pin Names and Descriptions

| Pin Name | Boundary Scan Order | Boundary Scan Function | Pin Description | 48-pin TSOP (VO48) | 48-pin TFBGA (FS48) |
|----------|---------------------|------------------------|---|--|--|
| TDO | | Data Out | JTAG Serial Data Output. This pin is the serial output for all JTAG instruction and data registers. TDO has an internal 50K Ω resistive pull-up to V _{CCJ} to provide a logic "1" to the system if the pin is not driven. | 22 | E6 |
| VCCINT | | | +1.8V Supply. Positive 1.8V supply voltage for internal logic. | 4, 15, 34 | B1, E1, G6 |
| VCCO | | | +3.3V, 2.5V, or 1.8V I/O Supply. Positive 3.3V, 2.5V, or 1.8V supply voltage connected to the output voltage drivers and input buffers. | 8, 30, 38, 45 | B2, C6, D6, G5 |
| VCCJ | | | +3.3V, 2.5V, or 1.8V JTAG I/O Supply. Positive 3.3V, 2.5V, or 1.8V supply voltage connected to the TDO output voltage driver and TCK, TMS, and TDI input buffers. | 24 | H2 |
| GND | | | Ground | 2, 7, 17, 23, 31, 36, 46 | A1, A2, B6, F1, F5, F6, H1 |
| DNC | | | Do Not Connect. (These pins must be left unconnected.) | 1, 3, 14, 16, 18, 35, 37, 39, 40, 41, 42 | A4, C3, C4, D3, D4, E3, E4, F2, F3, F4, G2 |

Revision History

The following table shows the revision history for this document.

| Date | Version | Revision |
|----------|---------|---|
| 04/29/03 | 1.0 | Xilinx Initial Release. |
| 06/03/03 | 1.1 | Made edits to all pages. |
| 11/05/03 | 2.0 | Major revision. |
| 11/18/03 | 2.1 | <p>Pinout corrections as follows:</p> <ul style="list-style-type: none">• Table 12:<ul style="list-style-type: none">- For VO48 package, removed 38 from VCCINT and added it to VCCO.- For FS48 package, removed pin D6 from VCCINT and added it to VCCO.• Table 13 (FS48 package):<ul style="list-style-type: none">- For pin D6, changed name from VCCINT to VCCO.- For pin A4, changed name from GND to DNC.• Figure 18 (VO48 package): For pin 38, changed name from VCCINT to VCCO. |
